

TransitOps Platform

Operational Workflows, Role Matrix & Architecture Guide

1. Executive Summary

TransitOps is a smart, full-stack transport operations platform designed to coordinate fleet management, trip logistics, driver dispatch, asset maintenance, and operational logs. By enforcing strict verification rules and embedding Gemini AI context views, the system provides real-time synchronization between dispatchers, drivers, maintenance crews, and administrators.

2. User Access & Role Matrix

The platform operates on a Role-Based Access Control (RBAC) hierarchy. Menu structures, page actions, and API endpoints are dynamically filtered based on these credentials:

Role Type	UI View Focus	Permissions & Scope
Administrator (ADMIN)	Control Center Theme (Violet) Full nav view + Admin Panel links	- Platform-wide database access - User management & driver profile verification - Analytics exports & cost auditing
Dispatcher (DISPATCHER)	Dispatch Console Theme (Blue) Trips, Drivers, and Vehicles registries	- Trip registry creation & dispatch assignment - Payload limit validations - Driver eligibility & license expiry overrides
Maintenance Manager (MAINTENANCE)	Fleet Workshop Theme (Amber) Maintenance requests, servicing records	- Repairs logging & completion hooks - Vehicle condition state changes - OOS (Out-of-service) triggers
Fleet Driver (DRIVER)	Driver Portal Theme (Emerald) Personal dispatch logs, fuel & expense logs	- Route GPS & status updates - Fuel receipts & strictly increasing odometer logs - Trip expense logs submission

3. Core Operational Workflows

3.1 Trip Dispatch Lifecycle

The primary workflow path for logistics operations follows a state-machine progression:

1. **Scheduling:** The Dispatcher matches a vehicle and driver for a specific route. Behind the scenes, validations confirm the driver's license is active (not expired) and that the cargo weight does not exceed the vehicle's max payload capacity.
2. **Activation:** Upon starting the trip, the state shifts to *In Progress*. This locks the vehicle status to *On Trip* and the driver to *On Trip*.
3. **Resolution:** The driver updates route logs. When complete, the dispatcher updates the state to *Completed* (which prompts for actual trip mileage update) or *Cancelled*. The vehicles and drivers are automatically returned to the *Available* roster.

3.2 Asset Maintenance & Safety Lifecycle

Ensures all vehicles are operating safely through automatic condition locking:

1. **Service Request:** Maintenance managers trigger a repair log for a specific vehicle.
2. **Locking:** The vehicle status is automatically updated to *Maintenance* (or *Out of Service* if critical) to block dispatchers from scheduling it for any new trips.
3. **Release:** Once maintenance works are completed and logged, the vehicle status reverts back to *Available* automatically.

3.3 Financial Logging & Verification Loop

Keeps fuel and general expenses synchronized with strict math checks:

- **Fuel Log Odometer Check:** Odometer inputs must exceed the vehicle's last recorded odometer reading. Successful logging automatically updates the vehicle's odometer value.
- **Cost Aggregation:** Expense logs (tolls, lodging, etc.) are matched with dispatch IDs, rolling up into the monthly financial audit views.

4. AI Copilot Integration

The platform embeds a Gemini 2.5 Flash assistant. When a user requests operations analysis, the system dynamically constructs a real-time fleet snapshot (counts of active trips, available drivers, maintenance tasks, and vehicles) and injects it as a system prompt instruction. This guarantees that answers regarding fleet utilization and scheduling are grounded in the actual database state.
